

## ANSWERS: Crystal ball questions on Explaining Polarity of molecules

Key points to consider for an Excellence grade are...

Does the molecule

- 1) contain polar bond(s), you must refer to a difference in electronegativity between the relevant atoms
- 2) contain lone pair(s) around the central atom
- 3) have a symmetrical shape
- 4) whether the polar covalent bonds (aka dipoles) cancel

<p style="text-align: center;"><b>CS<sub>2</sub></b></p> <p><b>CS<sub>2</sub></b> has non-polar molecules. The C–S bonds of CS<sub>2</sub> are polar due to the differing electronegativities of C and S atoms. However, as there are only 2 electron repulsions (2 bonding regions and no lone pairs) about the central C atom, the polar bonds are symmetrical about the C atom with a linear shape, and the effect of these polar bonds/bond dipoles is cancelled, so that the molecule is nonpolar.</p>	<p style="text-align: center;"><b>N<sub>2</sub></b></p> <p><b>N<sub>2</sub></b> has non-polar molecules. There is a triple bond between the 2 Nitrogen atoms, bonds between 1 N atom and another N atom are non- polar due to the exact same electronegativities of the 2 Nitrogen atoms. As there is only 1 region of electron repulsions between the 2 N atoms, the triple bond between the 2 N atoms is symmetrical with a linear shape so the molecule is nonpolar.</p> <p>other similar examples are O<sub>2</sub></p>	<p style="text-align: center;"><b>CH<sub>3</sub>OH</b></p> <p>In <b>CH<sub>3</sub>OH</b>, the polarity of the C–H bonds and the C–OH bonds are different; due to differences in electronegativity between the C, H and O atoms (the C–O bonds are more polar). There are 4 bonding regions of electron repulsion around the central C atom (with no lone pairs). Because of the higher electronegativity of the O atom, the charges are not spread evenly around the central C atom /the dipoles do not cancel, and the molecule is polar overall.</p>
<p style="text-align: center;"><b>HCN</b></p> <p><b>HCN</b> has polar molecules. The C–H and C–N bonds of HCN are polar due to the differing electronegativities of C, H and N atoms. However, as there are only 2 electron repulsions (2 bonding regions and no lone pairs) about the central C atom, the polar bonds are symmetrical about the C atom with a linear shape, and the effect of these polar bonds/bond dipoles is cancelled, so that the molecule is nonpolar.</p>	<p style="text-align: center;"><b>PCl<sub>3</sub></b></p> <p>In <b>PCl<sub>3</sub></b>, the P–Cl bonds are polar due to differences in electronegativity /dipoles of P and Cl atoms. The three polar P–Cl bonds are not spread symmetrically around the trigonal pyramid shaped molecule, due to the lone pair of electrons (there are 4 regions of electron density around the central P atom, 3 of these are bonding regions and 1 is a lone pair), therefore the molecule is polar.</p> <p>other similar examples are PH<sub>3</sub> and NBr<sub>3</sub></p>	

<p style="text-align: center;"><b>CH<sub>3</sub>COCH<sub>3</sub></b></p>  <p>There are 3 regions of electron density (3 bonding regions and no lone pairs) around the central carbon atom which results in a trigonal planar shape. However, there is an electronegativity difference between the carbon and oxygen atoms resulting in an uneven distribution of charge so the molecule is polar</p>	<p style="text-align: center;"><b>CH<sub>4</sub></b></p> <p>In <b>CH<sub>4</sub></b>, the C–H bonds are polar, due to differences in electronegativity of C and H atoms. However, four C–H bonds are arranged symmetrically in a tetrahedral shape (with 4 bonding regions and no lone pairs around the central atoms) and the charges are spread evenly, resulting in a non-polar molecule.</p>	<p style="text-align: center;"><b>C<sub>2</sub>H<sub>4</sub></b></p> <p>There is an electronegativity difference between the C and H atoms, however the central C atoms have no electronegativity difference between them. The carbon atoms in C<sub>2</sub>H<sub>4</sub> have three bonding regions (and no lone pairs) around them. This results in a trigonal planar shape. Since the molecule is symmetrical, there is an even distribution of charge and so the molecule is non-polar</p>
<p style="text-align: center;"><b>HCl</b></p> <p><b>HCl</b> has non-polar molecules. There is a single bond between the H and Cl atoms and a difference in electronegativity between the H and Cl atoms. The bond between the H and Cl atoms is non-symmetrical with a linear shape so the molecule is polar.</p>	<p style="text-align: center;"><b>SF<sub>2</sub></b></p> <p>In <b>SF<sub>2</sub></b>, the S-F bonds are polar, due to differences in electronegativity of S and F atoms. There are 4 regions of electron repulsion around the central S atom (2 bonding regions and 2 regions of lone pairs). The 2 lone pair of electrons on the S atom causes the SF<sub>2</sub> to occupy a bent or V shape around the central S. Therefore the effect of these polar bonds/bond dipoles is not cancelled, so that the molecule is polar.</p>	<p style="text-align: center;"><b>O<sub>3</sub></b></p>  <p><b>O<sub>3</sub></b> has polar molecules. The O–O bonds of O<sub>3</sub> are non-polar due to the exact same electronegativities between the O atoms. There are 3 electron repulsions (2 bonding and 1 lone) about the central O atom (trigonal planar). The lone pair of electrons on the O atom causes the O<sub>3</sub> to occupy a bent or V shape around the central S. Therefore the effect of these polar bonds/bond dipoles is not cancelled, so that the molecule is polar.</p>
